Glomus tumor in the abdominal wall

Tumor glômico de parede abdominal

ABSTRACT

The glomus tumor is a rare benign soft tissue tumor. We report a case of a 45-year-old male patient who presented with a painful mass in the abdominal wall. The patient underwent total tumor resection and the anatomical pathology diagnosis was of glomus tumor. The glomus tumor presents differential diagnosis of carcinoid tumor, hemangiopericytoma and vascular leiomyoma.

Key words: glomus tumor; abdominal wall; soft tissue tumors.

INTRODUCTION

The glomus tumor is a rare and benign soft tissue tumor. It is assumed that it originates from cells similar to the modified smooth muscle cells from the glomus body(1-3). Although it is more commonly found in the subungual region, it can also be found more rarely in places such as trachea, mediastinum, lungs, urinary bladder, skeletal muscle tissue and soft tissues(1, 4). It occurs, in general, in middle-aged women(1, 5).
**CASE REPORT**

A 45-year-old male patient presents painful nodular lesion on the abdominal wall. Total tumor resection was performed, and the material referred to pathological anatomy, whose gross-anatomy revealed a nodular lesion measuring 1.5 x 1.1 x 0.6 cm and microscopy, an encapsulated neoplasm consisting of round and small cells of eosinophilic cytoplasm and uniform nuclei, with no atypia, in solid block or arranged around blood vessels (Figures 1 and 2). Immunohistochemical analysis showed that the cells were positive for smooth muscle Actin (1A4), caldesmon (h-CALD) and type IV collagen (CIV 22). The final diagnosis was of glomus tumor.

**REFERENCES**

**DISCUSSION**

Glomus tumors account for about 1.6% of all soft tissue neoplasms (1). They are believed to originate from cells similar to the modified smooth muscle cells of a neuromyoarterial glomus, or glomus body, which is a form of arteriovenous anastomosis that may be associated with thermoregulation (1, 5). Surgical resection is usually curative, and recurrence of the lesion is rare (3).
